

## LOCATION OF SUBSCRIBER TERMINAL IN PACKET-SWITCHED RADIO SYSTEM

### FIELD

- 5 [0001] The invention relates to a method of performing a function of the subscriber terminal location service in a packet-switched radio system, and to a packet-switched radio system employing the method.

### BACKGROUND

- 10 [0002] Location of a subscriber terminal, i.e. determination of the geographical location of a subscriber terminal, is an important function in cellular radio networks. In the United States a federal authority (Federal Communication Commission FCC) requests that one should be able to locate all subscriber terminals that make emergency calls even with accuracy of 50 meters. Location can also be used for commercial purposes, e.g. for defining various tariff areas or for implementing a navigation service which guides the user. So far the location service (LCS) has been mainly developed for circuit-switched cellular radio networks, such as the GSM system (Global System Mobile Communications).

- 15 [0003] Various methods are used for implementing the location service. At the least accurate level the location of a subscriber terminal can be determined on the basis of the identity of the cell that serves the subscriber terminal. This does not provide very accurate information because the diameter of a cell can be dozens of kilometers.

- 20 [0004] A more accurate result is obtained by using timing information on the radio connection as additional information, e.g. the timing advance TA. In the GSM system the TA provides the location of a subscriber terminal with accuracy of approximately 550 meters. The problem is that if the cell is implemented with an omnidirectional antenna, the location of a subscriber terminal with respect to a base station is known only on the circumference drawn around the base station. A base station divided into three sectors, for example, slightly improves the situation, but even in that case it can only be determined that the subscriber terminal is located in a 120° sector in an area with a depth of 550 metres at a certain distance from the base station.

- 30 [0005] These inaccurate methods are adequate for some applications, e.g. for determining tariff areas. More accurate methods have also been developed. These methods are usually based on various base stations meas-

uring a signal transmitted by a subscriber terminal. One example of such methods is the TOA method (Time of Arrival).

- [0006]** The subscriber terminal can also measure signals transmitted by various base stations. An example of such a method is the E-OTD method (Enhanced Observed Time Difference). In synchronized networks the subscriber terminal measures the ratios between the reception moments of the signals it has received from different base stations. In non-synchronized networks the signals transmitted by the base stations are also received by a location measurement unit LMU placed at a known and fixed measurement point.
- 10 The location of the subscriber terminal is determined on the basis of geometrical components obtained from time delays.

- [0007]** Another location method is to use a GPS receiver (Global Positioning System) arranged in a subscriber terminal. The GPS receiver receives a signal transmitted by at least four earth-orbiting satellites, and the latitude, longitude and altitude of the location of the subscriber terminal can be calculated on the basis of these signals. The subscriber terminal either determines the location independently or it is assisted in the determination. The network part of the radio system may send an assistance message to the subscriber terminal, which speeds up the location process, i.e. the power consumption of the subscriber terminal decreases. The assistance message may contain the time, a list of visible satellites, Doppler shift of the satellite signal and a search window for the code phase. The subscriber terminal can send the information it has received to the network part, in which the location is calculated. In this application the network part of the radio system refers to the fixed
- 15 part of the radio system, i.e. to the whole system except for the subscriber terminal.
- 20
- 25

- [0008]** In packet-switched radio systems, like in the GPRS (General Packet Radio Service) or in the EGPRS (Enhanced General Packet Radio Service), very little attention has been paid to the implementation of the location service. The EGPRS is a GSM-based (Global System for Mobile Communications) system which utilizes packet-switched transmission. The EGPRS employs the EDGE (Enhanced Data Rates for GSM Evolution) technique for increasing the data transmission capacity. In addition to the GMSK modulation (Gaussian Minimum-Shift Keying) normally used in the GSM, the 8-PSK modulation (8-Phase Shift Keying) can also be applied to packet data channels. The
- 30
- 35
- main object is to provide non-real-time data transmission services, such as

copying of files and use of an Internet browser, but also packet-switched real time services for transmission of speech and video, for example.

- 5       **[0009]** In packet-switched radio systems the location methods described above require a packet-switched transmission connection between the core network of the radio system and the subscriber terminal for transmitting the necessary information. The signaling traffic needed is rather heavy and slow. In time critical applications it would, however, be important to receive the location of the subscriber terminal fast from the location service.

#### BRIEF DESCRIPTION OF THE INVENTION

- 10       **[0010]** An object of the invention is to provide an improved method of performing a function of the subscriber terminal location service in a packet-switched radio system. According to an aspect of the present invention, there is provided a method of claim 1 of locating a subscriber terminal in a packet-switched radio system. According to another aspect of the invention, there is  
15       provided a packet-switched radio system of claim 18. The preferred embodiments of the invention are disclosed in the dependent claims.

- [0011]** The invention is based on adding information needed by a function of the location service to a request message or to a new response message.  
20       **[0012]** Several improvements are achieved with the method and apparatus of the invention: the location method becomes faster, in certain cases no packet-switched transmission connection needs to be established at all, and the amount of signaling needed decreases.

#### BRIEF DESCRIPTION OF THE DRAWINGS

- 25       **[0013]** The invention will be described in greater detail by means of preferred embodiments with reference to the accompanying drawings, in which  
      **[0014]** Figure 1A shows an example of the structure of a cellular radio network;  
      **[0015]** Figure 1B is a block diagram illustrating the cellular network  
30       in greater detail;  
      **[0016]** Figure 1C illustrates a circuit-switched connection;  
      **[0017]** Figure 1D illustrates a packet-switched connection;  
      **[0018]** Figure 2 shows an example of protocol stacks used in certain parts of the cellular radio network;

[0019] Figure 3 is a flow chart illustrating a method of performing a function of the subscriber terminal location service;

[0020] Figure 4 is a signal sequence chart related to Figure 3 illustrating an example of the performance of the location function.

## 5 DESCRIPTION OF EMBODIMENTS

[0021] The typical structure of a packet-switched radio system and its connections to a public switched telephone network and packet transmission network will be described with reference to Figures 1A and 1B. Figure 1B includes only the blocks necessary for describing the embodiments, but it is clear to a person skilled in the art that a conventional packet-switched cellular radio network also comprises other functions and structures that need not be described in greater detail here. The radio system may be e.g. the GSM-based GPRS or EGPRS system, the universal mobile telephone system UMTS, which utilizes the wideband code division multiple access method, or an intermediate form of these systems, in which the structure of the radio network is similar to that of the UMTS and which is called e.g. GERAN (GSM Enhanced Radio Access Network). In such a system the radio interface is, however, a normal GSM-based radio interface or a radio interface which uses EDGE modulation.

[0022] The description of Figures 1A and 1B is mainly based on the UMTS. The main parts of the mobile communications system are a core network CN, an UMTS terrestrial radio access network, i.e. the radio network UTRAN, and user equipment UE. The interface between the CN and the UTRAN is called Iu, and the air interface between the UTRAN and the UE is known as Uu.

[0023] The UTRAN consists of radio network subsystems RNS. The interface between the RNSs is called Iur. The RNS consists of a radio network controller RNC and of one or more B nodes. The interface between the RNC and the B is called Iub. The coverage area of the B node, i.e. a cell, is marked with C in Figure 1B. The more conventional name, i.e. base station system BSS, can also be used for the RNS. The network part of the radio system thus comprises the radio network UTRAN and the core network CN.

[0024] The illustration of Figure 1A is very abstract, and thus it is specified in Figure 1B by showing which part of the GSM system approximately corresponds to which part of the UMTS. It should be noted that the de-

scription is not limiting but only indicative because the responsibilities and functions of the different parts of the UMTS are still under design.

[0025] The subscriber terminal 150 may be fixed, placed in a vehicle or a portable terminal. The infrastructure of the radio network UTRAN consists of radio network subsystems RNS, i.e. base station systems. The radio network subsystem RNS consists of radio network controllers RNC, i.e. of a base station controller 102 and of at least one B node, i.e. a base station 100, controlled by it.

[0026] The base station B contains a multiplexer 116, transceivers 114 and a control unit 118, which controls the function of the transceivers 114 and the multiplexer 116. The multiplexer 116 is used for arranging the traffic and control channels used by several transceivers 114 on one transmission connection 160.

[0027] From the transceivers 114 of the base station B there is a connection to an antenna unit 112, which establishes a bi-directional radio connection Uu to the subscriber terminal 150. The structure of the frames to be transmitted on the bi-directional radio connection Uu is strictly defined.

[0028] The base station controller RNC comprises a switching field 120 and a control unit 124. The switching field 120 is used for switching speech and data and for connecting signaling circuits. A base station system formed by the base station B and the base station controller RNC also includes a transcoder 122. The division of tasks between the base station controller RNC and the base station B and the physical structure may vary according to the application. Typically the base station B implements the radio path as described above. The base station controller RNC is typically responsible for the following: radio resource management, handover control, power control, timing, synchronization and paging of a subscriber terminal.

[0029] The transcoder 122 is usually located as close to a mobile services switching center 132 as possible because this saves transmission capacity when speech is transmitted in the format of a cellular radio network between the transcoder 122 and the base station controller RNC. The transcoder 122 converts the different digital speech encoding formats used between the public switched telephone network and the radio telephone network into a compatible format, e.g. from the 64 kbits/s format of the fixed network into a format of the cellular radio network (e.g. 13 kbit/s), and vice versa. The devices needed are not described in greater detail here, but it should be

noted that other data than speech are not converted in the transcoder 122. The control unit 124 is responsible for call controlling, mobility management, collection of statistics and signaling.

5       **[0030]** The core network CN consists of infrastructure belonging to a mobile communications system external to the UTRAN. Figure 1B illustrates a mobile services switching center 132, which is one of the devices belonging to circuit-switched transmission of the core network CN.

10       **[0031]** As is seen in Figure 1B, the switching field 120 can establish connections (illustrated with black dots) both to a public switched telephone network PSTN 134 via the mobile services switching center 132 and to a packet transmission network 142. In the public switched telephone network 134 a typical terminal 136 is a conventional telephone or an ISDN telephone (Integrated Services Digital Network). Packet transmission is performed from a computer 148 connected to the mobile communication system via the Internet  
15       146 to a portable computer 152 connected to the subscriber terminal 150. A WAP phone (Wireless Application Protocol) can also be used instead of the combination of the subscriber terminal 150 and the portable computer 152.

20       **[0032]** The connection between the packet transmission network 142 and the switching field 120 is established by a support node 140 (SGSN = Serving GPRS Support Node). The function of the support node 140 is to transmit packets between the base station system and a gateway node (GGSN = Gateway GPRS Support Node) 144 and keep a record of the location of the subscriber terminal 150 in its area.

25       **[0033]** The gateway node 144 connects a public packet transmission network 146 and the packet transmission network 142. An Internet protocol or an X.25 protocol can be used at the interface. The gateway node 144 hides the internal structure of the packet transmission network 142 from the public packet transmission network 146 by encapsulating the structure, and thus the public packet transmission network 146 regards the packet transmission network 142 as a sub-network which comprises a subscriber terminal 150  
30       to which the public packet transmission can send packets and receive packets from it.

35       **[0034]** The packet transmission network 142 is typically a private network which utilizes the Internet protocol and carries signaling and user data. The structure of the network 142 may vary according to the operator in respect of its architecture and protocols below the Internet protocol layer.

**[0035]** The public packet transmission network 146 may be e.g. the worldwide Internet network, there being a terminal 148, e.g. a server computer, connected to the Internet which wants to transmit packets to the subscriber terminal 150.

5 **[0036]** Figure 1C illustrates how a circuit-switched connection is established between the subscriber terminal 150 and the terminal 136 of the public switched telephone network. The bold line in the figures illustrates how data passes through the system at the air interface 170 from the antenna 112 to the transceiver 114 and from the transceiver in a form multiplexed in the multiplexer 116 over a transmission connection 160 to the switching field 120, where a connection is established to the output towards the transcoder 122, and further to the terminal 136 connected to the public switched telephone network 134 through switching performed at the mobile services switching center 132. In the base station 100 the control unit 118 controls the multiplexer 15  
10 116 in performing of transmission, and in the base station controller 102 the control unit 124 controls the switching field 120 in performing of correct switching.

**[0037]** Figure 1D illustrates a packet-switched transmission connection. A portable computer 152 is connected to the subscriber terminal 150. The bold line describes how the data to be transmitted is carried from the server computer 148 to the portable computer 152. Information can naturally also be transmitted in the opposite transmission direction, that is, from the portable computer 152 to the server computer 148. Data passes through the system at the air interface, i.e. at the Um interface 170, from the antenna 112 to the transceiver 114 and from the transceiver in a form multiplexed in the multiplexer 116 over a transmission connection 160 at the Abis interface to the switching field 120, where a connection is established to the output towards the support node 140 at the Gb interface. From the support node 140 the data is transmitted along the packet transmission network 142 via the gateway node 20 25 30 144 to the server computer 148 connected to the public packet transmission network 146.

**[0038]** For the sake of clarity Figures 1C and 1D do not illustrate a case in which both circuit-switched and packet-switched data are transmitted at the same time. This is, however, feasible as well as common since capacity freed from transmission of circuit-switched data can be flexibly used for packet-switched transmission. It is also possible to build a network on which only 35

packet-switched data is transmitted, i.e. no circuit-switched data. In that case the network structure can be simplified.

[0039] We will now return to Figure 1D. The different entities of the UMTS system, i.e. CN, UTRAN, RNS, RNC, B, are illustrated with broken line boxes in the figure. Devices of the core network CN that belong to packet-switched transmission will also be described in greater detail. In addition to the support node 140, packet transmission network 142 and gateway node 144, the core network comprises a gateway mobile location center GMLC 186 and a home location register HLR 184. The function of the gateway mobile location center is to offer the requested service to an outside client 188 of the location service. The home location register 184 includes subscriber data of the location service and routing information.

[0040] Figure 1D shows a serving mobile location center 182, which is one of the devices needed by the location service and may be located, as shown, in the base station controller RNC, e.g. in its control part 124, or which may be a separate device connected either to the base station controller RNC or to the support node 140. The figure also shows a location measurement unit LMU 180, which may be in the base station B, e.g. in its control part 118, or which may be a separate device connected to the base station B. The function of the location measurement unit 180 is to perform any radio measurements needed in the location method.

[0041] Figure 1D also shows those structural parts of the subscriber terminal UE that are relevant to the present embodiment. The subscriber terminal UE comprises an antenna 190, via which a transceiver 192 receives a signal from the radio path 170. The function of the subscriber terminal UE is controlled by a control part 194, which is typically a microprocessor provided with the necessary software. The protocol procedures to be described later are also performed by this software. In addition to the above-mentioned parts, the subscriber terminal UE comprises a user interface, which typically consists of a loudspeaker, microphone, screen and keyboard, and a battery. These are not described more closely because they are irrelevant to the present invention.

[0042] Neither the structure of the transceiver in the base station B nor the structure of the transceiver in the subscriber terminal UE is described more closely because it is clear to a person skilled in the art how these devices are implemented. For example, a normal radio network transceiver and a subscriber terminal transceiver in accordance with the EGPRS can be used. The

only thing that is important to the present embodiment is that the radio connection 170 can be implemented, since the function required by the application is performed at upper levels of the OSI model (Open Systems Interconnection), particularly in the third layer.

5       **[0043]** Figure 2 illustrates control plane protocol stacks of the EGPRS. It should be noted that the embodiments are not limited to the EGPRS. The protocol stacks have been formed according to the OSI model (Open Systems Interconnection) of the ISO (International Standardization Organization). In the OSI model protocol stacks are divided into layers. In principle, there may be seven layers. Figure 2 shows which protocol sections are processed in each network element. The network elements illustrated in the figure are a subscriber terminal MS, a base station system BSS, a support node SGSN and a gateway node GGSN. The base station and the base station controller are not illustrated separately because an interface has not been defined between them. In principle, the protocol handling defined for the base station system BSS can be divided freely between the base station 100 and the base station controller 102, but in practice not between the transcoder 122, even though it belongs to the base station system BSS. Different network elements are separated by interfaces Um, Gb and Gn between them.

20       **[0044]** The layer in each device MS, BSS, SGSN, GGSN communicates logically with a layer in another device. Only the lowest physical layers communicate directly with one another. The other layers always use the services provided by the next lower layer. Thus a message has to physically travel in the vertical direction between the layers, and only in the lowest layer the message travels in the horizontal direction between the layers.

25       **[0045]** The actual bit-level data are always transmitted using the first physical layer RF, L1. The mechanical, electric and functional properties needed to access a physical transmission path are defined in the physical layer. The second layer, i.e. the data link layer, uses the services of the physical layer to provide reliable data transmission, and corrects e.g. transmission errors. At the air interface 170 the data link layer is divided into an RLC/MAC sub-layer and an LLC sub-layer. The third layer, i.e. the network layer, provides the upper layers with independence from data transmission and switching techniques, which are used for establishing a connection between the devices. The network layer is responsible for establishment, maintenance and release of a connection, for example. In the GSM the network layer is also

called a signaling layer. It has two main functions: it routes messages and enables several independent connections between two entities at the same time.

**[0046]** The network layer comprises a session management SM sub-layer and a GPRS mobility management GMM sub-layer.

5 **[0047]** The mobility management sub-layer GMM takes the consequences that result from the fact that the user of the subscriber terminal moves and are not directly related to the management of radio resources. In the fixed network this sub-layer would check the user's rights and connect the user to the network. In cellular radio networks this sub-layer thus supports user mobility, registration and management of mobility data. This sub-layer also checks  
10 the identity of the subscriber terminal and the identities of allowed services. In this sub-layer messages are transmitted between the subscriber terminal MS and the support node SGSN.

**[0048]** The session management sub-layer SM manages all functions related to the management of a packet-switched call but it does not detect user mobility. The session management sub-layer SM establishes, maintains and releases connections. It has separate procedures for calls originating from the subscriber terminal 150 and for calls terminating to the subscriber terminal. In this sub-layer messages are also transmitted between the sub-  
20 scription terminal MS and the support node SGSN.

**[0049]** In the base station system BSS the messages of the session management sub-layer SM and the mobility management sub-layer GMM are processed transparently, i.e. they are only transferred to and fro.

**[0050]** The LLC layer (Logical Link Control) provides a reliable logical encryption link between the SGSN and the MS. The LLC is independent of  
25 the lower layers, which allows to minimize the effect of changes in the air interface on the network part of the mobile communications network. The information to be transmitted and the user data are encrypted. Between the Um and the Gb interfaces the LLC data is transmitted at the relaying level LLC RELAY  
30 of the LLC.

**[0051]** The MAC level (Medium Access Control) is responsible for the following tasks: multiplexing of data and signaling both in the uplink (from the subscriber terminal towards the network part) and in the downlink (from the networks part towards the subscriber terminal), management of resource requests in the uplink and allocation of resources and timing of traffic in the downlink. Management of traffic prioritization also belongs to this level. The  
35

RLC level (Radio Link Control) transmits data of the LLC level, i.e. LLC frames, to the MAC level; the RLC splits the LLC frames into RLC data blocks, which it transmits to the MAC layer. In the uplink direction the RLC forms LLC frames from the RLC data blocks and transmits them to the LLC layer. The physical level is implemented with a radio connection at the Um interface, e.g. at the air interface defined for the GSM. At the physical level the following tasks, for example, are performed: modulation of the carrier wave, interleaving and error correction of the data to be transmitted, synchronization, and power control of the transmitter.

10           **[0052]** The GPRS tunneling protocol GTP tunnels the signaling along the trunk network between different SGSNs and GGSNs. If desired, the GTP can control the flow between the SGSN and the GGSN.

15           **[0053]** The user datagram protocol UDP transmits the GTP layer data packets whose protocol does not require a reliable link, e.g. when the Internet protocol IP is used. At the user level a TCP (Transmission Control Protocol) could also be used, which controls the flow of the packets transmitted via it and protects them against disappearance and corruption. The UDP protects the packets only against corruption.

20           **[0054]** The IP is a trunk network protocol of the GPRS, which routes user data and control data. The IP may be based on the IPv4 protocol, but in a later phase this will be replaced with the Ipv6 protocol.

25           **[0055]** In addition to the upper level data, the BSSGP plane (Base Station Subsystem GPRS Protocol) carries information on routing and quality of service between the BSS and the SGSN. This information is physically carried by the FR level (Frame Relay). The NS (Network Service) transmits the messages in accordance with the BSSGP protocol.

30           **[0056]** In the following, we will exemplify with reference to Figures 3 and 4 how a function of the subscriber terminal location service is performed when the subscriber terminal requests it. Figure 3 is a flow chart illustrating the functions to be performed in the basic method, and Figure 4 is a signal sequence chart illustrating different embodiments of the method.

35           **[0057]** The method starts in block 300. In block 302 the subscriber terminal MS sends a request message 400 for location service via the radio network, which is the base station system BSS in our example, to the core network, which is the support node SGSN in our example. If desired, security procedures can be performed after this, e.g. identification of the subscriber

terminal, according to the prior art. For the sake of clarity, these security procedures are not shown in Figures 3 and 4.

**[0058]** Next at least one function of the location service requested in the message 400 is performed according to block 304. The request message relates to one of the following location service functions: determination of the subscriber terminal location, informing an outside client of the radio system of the subscriber terminal location, transmission of location assistance data to the subscriber terminal, or transmission of a ciphering key for decrypting the location assistance data to the subscriber terminal.

**[0059]** Determination of the subscriber terminal location means that the geographical location of the subscriber terminal is found out and given as longitude or latitude, for example. The location is needed by the subscriber terminal, i.e. its user, or by an outside client of the location service in the radio system. The route traveled by the subscriber terminal is traced so that the subscriber terminal at regular intervals sends a message to the core network requesting determination of the location of the subscriber terminal.

**[0060]** The location assistance data refers e.g. to the assistance message which was described at the beginning and includes information on how the GPS system can be used more efficiently. Such assistance messages can be sent on the broadcast channel of the system and their use is chargeable. For this reason, the assistance messages can be encrypted, in which case the subscriber terminal has to request a ciphering key for decrypting the messages from the network.

**[0061]** Information of various kinds can be inserted into the request message 400. The information included in the request message 400 comprises the identity of the serving cell, and/or timing information on the radio connection and/or other information on the radio system or the subscriber terminal, and/or the desired quality of service of the requested location service, and/or the telecommunications address, e.g. the IP address, of the outside client who wants location information on the subscriber terminal. The timing information includes a timing advance factor or the round trip time. The other information that can be used includes at least one of the following parameters: receiving power of the serving cell, receiving power of at least one neighboring cell, charge level of the battery in the subscriber terminal, information on the conditions at the location of the subscriber terminal, such as the temperature, and

identity of a separate device connected to the subscriber terminal, such as the IP address.

**[0062]** At least part of the information included in the request message received by the core network has been inserted into the request message by the subscriber terminal, and/or at least part of the information included in the request message received by the core network has been inserted into the request message by the radio network.

**[0063]** When the desired function is location of the subscriber terminal, a special location procedure is performed. Figure 4 illustrates one example of how the location function can be performed. The support node SGSN sends a location request 402 to the base station subsystem BSS, which forwards this request 404 to the location center SMLC. The network part of the radio system, which is represented by the SMLC in our example, can locate the subscriber terminal on the basis of the information included in the request message, using e.g. the timing advance factor and the cell identity.

**[0064]** According to block 406, the network part, i.e. the function in the SMLC in our example, checks whether the location of the subscriber terminal carried out corresponds to the target set for the quality of service. If the target set for the quality of service is not achieved, we will move to block 412 according to arrow 410, where the network part performs a location service which provides a better quality of service. If the target set for the quality of service is achieved, we will move to block 414 according to arrow 508, where a message 414 informing the base station system of the location of the subscriber terminal is sent, and the base station system forwards this information 416 to the support node SGSN of the core network.

**[0065]** Initiation of the location service in the subscriber terminal at the same time as the request message 400 is sent may further performance of the location service that provides a better quality of service in block 400. According to block 412, the communication needed is performed using a packet-switched connection between the SMLC, the BSS and the MS so that the location service with a better quality can be performed. The content of the messages concerned naturally depends on the location method used. The location methods described at the beginning, e.g. the TOA method or the E-OTD method, can be used, depending on which is supported by the radio system and the subscriber terminal. After the location with a better quality has been performed, we can return to block 406, where the quality of service is tested again. In principle, the quality of the location service can be improved

again. In principle, the quality of the location service can be improved with several iteration cycles. In the example of Figure 4 it is assumed that a sufficient quality of service is achieved with one iteration cycle, i.e. that if functions included in block 412 have been performed, then we will move directly from block 412 to transmission of the location information message 414.

[0066] The measures required by the location service with a better quality include reception of signals in the subscriber terminal, and measurement of the signals or transmission of signals from the subscriber terminal. For implementation of the location service, the signals to be received in the subscriber terminal also comprise signals transmitted by other base stations of the radio system than by that of the serving cell, or the signals transmitted by a satellite of the GPS system.

[0067] After the SGSN has received the message 416 including the location of the subscriber terminal, it transmits this information 418 to the GMLC, which sends an acknowledgement message 420.

[0068] Next it is checked in the GMLC in block 422 whether an outside client LCS CLIENT of the location service wants to have information on the location of the subscriber terminal. If an outside client wants the location information, we will move according to arrow 424 to transmission of the message 428 including the location information to the outside client.

[0069] An outside client of the radio system is informed of the location of the subscriber terminal by the core network GMLC, by the subscriber terminal MS itself, or together by the core network GMLC and the subscriber terminal MS. The core network GMLC may independently inform an outside client of the location, provided that the GMLC database includes a valid order for this information. The subscriber terminal itself may also give the information to a desired outside party. In that case the subscriber terminal has to establish a normal packet-switched transmission connection for transmitting this information. Cooperation between the GMLC and the subscriber terminal can be implemented e.g. so that the subscriber terminal gives the telecommunications address, e.g. the IP address, of the outside client who wants information on the subscriber terminal location in the request message 400, and having received the location information, the GMLC sends a message 418 including the location and the telecommunications address to the client. The message may also contain the identity of a separate device connected to the subscriber terminal, such as the IP address.

[0070] After the desired function or functions have been performed, the core network SGSN transmits a response message 430 to the request message 400 to the subscriber terminal via the radio network. Then the method is finished in block 308. The response message contains at least one of the following pieces of information: the location of the subscriber terminal, location assistance data, a ciphering key for decrypting the location assistance data, an error code, information on whether the subscriber terminal location information is to be supplied to an outside client. The request message and the response message are messages of the protocol layers that correspond to the third layer of the OSI model.

[0071] Compared to the prior art, the new features are implemented preferably by software, and thus the location method requires relatively simple software changes to precisely defined functions in the core network, radio network and subscriber terminal. The subscriber terminal UE comprises means 194 for transmitting a request message for location service to the core network CN via the radio network RAN. The core network CN comprises means for performing at least one of the functions required in the request message and means for transmitting a response message to the subscriber terminal UE via the radio network RAN. The means can also be implemented as software to be performed in a general-purpose processor. The invention can also be implemented by hardware, e.g. as an ASIC (Application Specific Integrated Circuit) or as control logic consisting of separate components.

[0072] Even though the invention has been described with reference to the example according to the accompanying drawings, it is clear that the invention is not limited thereto but may be modified in various ways within the inventive concept disclosed in the appended claims.
